

Module 10: Deploying Flask Apps with GCP Cloud Run

Overview

This guide walks you through deploying a Dockerized Flask application to Google Cloud Platform's Cloud Run service with continuous deployment from GitHub.

Step 1: Set Up Your Repository

Start by creating your own copy of the base repository:

Base Repo: <https://github.com/hantswilliams/dokploy-docker-flask>

Important: You must create your own version of this repo. If you try to clone the original, you won't have permission to push changes. You have two options:

- **Option A:** Fork the repository to your GitHub account
- **Option B:** Manually copy the files into a new repository you create

Step 2: Create a Cloud Run Service

2.1 Start the Service Creation

1. Navigate to **Cloud Run** in the GCP Console
2. Click **Create Service**
3. Click the **Connect Repo** button (with the GitHub logo)

2.2 Configure Repository Connection

Select "**Continuously deploy from a repository (source or function)**" as shown below:

2.3 Set Up Developer Connect

- 1. Select **Developer Connect** — this will walk you through granting GCP permission to access your GitHub repos
- 2. After completing the Developer Connect setup and confirming you can see your GitHub repos, **stop and restart from Step 2.1**

Note: There can be a slight delay between the GitHub connection and GCP recognizing it. Restarting the process helps ensure everything is properly synced.

- 3. Click the blue "**Set up with Developer Connect**" button to select the repo containing your Dockerfile

2.4 Configure Service Settings

Setting	Value
Service name	Any name you prefer
Region	Choose one you have access to
Authentication	Allow unauthenticated invocations (public access)
Billing	Request-based

2.5 Configure Autoscaling & Container

Setting	Value
Maximum instances	1 (to limit costs from bots)
Container port	Match the port set in your Dockerfile
Revision scaling maximum	1

Leave all other container settings at their defaults.

Deployment Complete

Once configured, Cloud Run will automatically build and deploy your application whenever you push changes to your connected GitHub repository.
